EFFECTS OF MANNANOLIGOSACCHARIDE AND SODIUM CHLORATE ON GROWTH PERFORMANCE OF NURSERY PIGS DURING AN ACUTE ENTERIC DISEASE CHALLENGE WITH \textit{Salmonella enterica} SEROTYPE TYPHIMURIUM

\textit{T. E. Burkey, S. S. Dritz$^1$, J. C. Nietfeld$^2$, B. J. Johnson, and J. E. Minton}

Summary

A 28-day experiment was conducted to compare the effects of feeding mannanoligosaccharides (mannan) and sodium chlorate (chlorate) to weanling pigs as a possible substitute for the commonly used antimicrobial carbadox. Pigs were fed experimental diets for 2 wk, then challenged orally with \textit{Salmonella enterica} serotype typhimurium to establish enteric disease. Average daily gain and ADFI were greater for pigs fed carbadox than all other treatments in the 2 wk following infection. During the first week after infection, pigs fed chlorate had greater G/F than control pigs, and pigs fed mannan tended to have greater G/F than control pigs. There were no differences in feed efficiency among treatments during the second week following infection.

(Key Words: Mannanoligosaccharides, Sodium Chlorate, Antimicrobials, Weanling Pigs.)

Introduction

Dietary mannan has been shown to enhance growth performance in nursery-aged swine. Mannan may also directly affect gut health in pigs. Another novel feed additive for pigs that shows promise is chlorate, which appears to be effective in reducing the pathogenesis and shedding of \textit{Salmonella} organisms in pigs. In a recent preliminary report, feeding weaned pigs up to 0.04 g chlorate/kg body weight reduced the number of pathogenic organisms in the intestines by 150-fold. Thus, feeding of chlorate short term appears to offer potential as a preharvest food safety tool to reduce \textit{Salmonella} in the gastrointestinal tract of pigs prior to transport. However, the effect of chronic feeding of chlorate to pigs on growth performance and other physiological parameters has not been evaluated.

The current study was designed to evaluate growth in pigs fed mannan or chlorate prior to and after enteric disease challenge with \textit{Salmonella enterica} serotype typhimurium. Although statistically it was possible to compare the effectiveness of mannan versus chlorate, the primary objective was to compare each of the additives individually to either feeding a diet without antimicrobial or to pigs fed diets containing the commonly fed antimicrobial carbadox.

Procedures

Weaned pigs (n=96) were blocked by weight and assigned randomly within blocks to four dietary treatments. The negative control diet contained neither of the two additives or carbadox, while the positive control contained carbadox (55 ppm; Table 1). Test diets

contained mannan (1500 ppm) or chlorate (800 ppm). None of the diets contained other anti-
microbial agents. There were 12 pens per
treatment with 2 pigs/pen. Pigs were fed diets
for 2 wk and then all pigs were given $1.33 \times 10^9$
CFU *S. enterica* serotype typhimurium orally
and the study continued for an additional 2 wk.
Body weights were obtained weekly and feed
consumption was measured to estimate average
daily gain (ADG), feed intake (ADFI) and feed
efficiency (G/F).

**Results and Discussion**

During week 1 of the study, pigs fed the
carbadox grew faster than pigs fed the chlorate
diet ($P<0.05$), and in week 2 carbadox fed pigs
had greater ADG than pigs fed the mannan or
chlorate treatments ($P<0.05$; Figure 1). In week
2, this enhancement in performance was
associated with increased ADFI in carbadox fed
pigs ($P<0.05$). In week 3, the week following
bacterial challenge, negative control pigs had
reduced ADG, ADFI, and G/F compared to
carbadox-fed pigs ($P<0.05$). During this same time
pigs fed chlorate had greater ADG and G/F than
negative control pigs ($P<0.05$), although ADG
during that time was less than carbadox-fed pigs
($P<0.05$). During week 3, pigs fed mannan
tended to have improved G/F relative to
negative control pigs ($P<0.07$). Pigs fed the
carbadox treatment maintained greater ADG
and ADFI than all other treatments during week
4.

Data from the current study are generally
consistent with the growth benefits associated
with feeding antimicrobials both prior to and
following challenge with an enteric pathogen. In
general, the pigs fed mannan and chlorate
performed similarly to pigs fed no added anti-
microbial. However, both mannan and chlorate
tended to improve G/F in the week following
bacterial challenge and this may suggest
improved gut function in the face of the
pathogenic insult. In addition, it is clear that this
model of enteric disease provides a robust
experimental setting in which to test potential
alternatives to conventional antimicrobial feed
additives for pigs.
